Midpoint (RK2) Method

© Omar Gamal's Report

Izhikevich model and midpoint method

The Izhikevich model equations considered as Stiff ODEs where certain components of the solution change on a much faster timescale than others, leading to numerical instability or inefficiency when solved with standard methods like the explicit Euler or **midpoint** (**RK2**) **method** as the Explicit methods like **RK2** are generally not well-suited for stiff ODEs because they require extremely small step sizes (h) to remain stable, especially when the system exhibits rapid changes (e.g., the spikes in v when it exceeds 35 in your simulation)

- How to handle Stiff ODEs effectively (suggestions for improvements)
 - 1. Variable Step Size and Adaptive Methods: Use adaptive step-size control to adjust (h) dynamically based on the local stiffness
 - 2. Analyze and Adjust Model Parameters: Check the parameters (e.g., C=100 C=100 C=100, k=0.7 k=0.7 k=0.7, a=0.03 a=0.03 a=0.03) and initial conditions ($v0=-60 v_0=-60 v_0=-60$, $w0=0 w_0=0$ for sources of stiffness. Reducing h h h (e.g., to 0.1 ms) or adjusting a a a (recovery speed) might mitigate some stiffness
 - ➤ The Problem solved using midpoint method

$$Cdv/dt = k(v-vr)(v-vt)-w+In$$

 $dw/dt = a[b(v-vr)-w]$

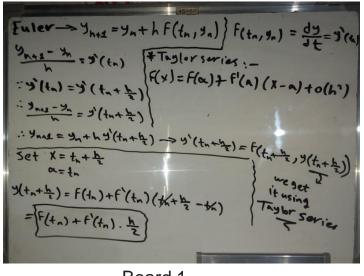

> Parameters used:

- C (Capacitance) = 100
- k (Voltage scaling factor) = 0.7v
- Vr (Resting potential) = -60
- Vt (Threshold potential) = -40
- a (Recovery speed) = .03
- $b ext{ (Coupling } v ext{ to } w) = -2$
- d (Amount to increase w after spike) = 100
- Vpeak (Peak threshold) = 35
- In (Constant input current) \rightarrow if iteration < 101, In = 0, else In = 70
- v (neuron membrane potential)
- w (recovery current)
- Wo (initial value of w) = o
- Vo (initial value of v) = -60

- ➤ Midpoint method (RK2) equations
- 1. $K_{1v} = F_v (W_n, V_n)$
- 2. $K_{1v} = F_v (W_n, V_n)$
- 3. $V_{mid} = V_n + (h/2) * K_{1v}$
- 4. $W_{mid} = W_n + (h/2) * K_{1w}$
- 5. $K_{2v} = F_v(V_{mid}, W_{mid})$
- 6. $K_{2w} = F_w(V_{mid}, W_{mid})$
- 7. $V_{n+1} = V_n + h * K_{2v}$
- 8. $W_{n+1} = W_n + h * K_{2w}$
- ➤ How to use the method :
 - 1. Calculate K_{1v} and K_{1w} using the calculations mentioned above (Step 1)
 - 2. Calculate V_{mid} , W_{mid} using the calculations form Step 1 (Step 2)
 - 3. Calculate K_{2v} , K_{2w} using the calculations from Step 2 (Step 3)
 - 4. Calculate V_{n+1} , W_{n+1} using the calculations from step 3 (Step 4)
 - 5. Repeat the steps (starting from step 1) as $V_n = V_{n+1}$ and $W_n = W_{n+1}$, only if V_{n+1} didn't exceed the spike value but if it does then $V_n = c = -50$, $W_{n+1} = W_{n+1} + d$

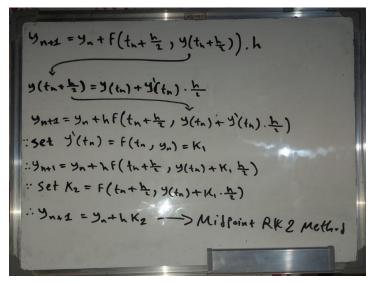

➤ The Derivation of the midpoint method

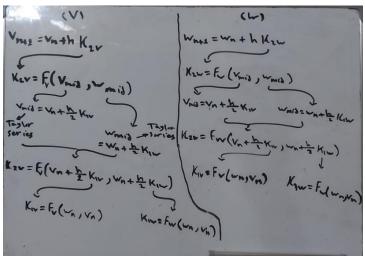

The midpoint method is a refnement of the Euler Method

 y_{n+1} $t_n + h/2$

Board 1

Board 2

Board 3

Board 1 and Board 2

In Board No.1 and Board No.2, We try to conclude the equation of Midpoint method in terms of one variable (Which is y)

Board 3

In Board No.3, We try to conclude the equation of Midpoint method in terms of 2 variables which are (v, w), these equations are the one used to solve the given problem

Code of Izhikevich model using Midpoint method :

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
def midpoint_method(v_old , w_old , h_value , num_iter):
    v_old_values = []
    v_new_values = []
    w_old_values = []
    w_new_values = []
    k_1_v_values = []
    k_1_w_values = []
    k_2_v_values = []
    k_2_w_values = []
    iterations = []
    c = 100
    k = .7
    v_r = -60
    v_t = -40
    a = .03
    b = -2
    d = 100
    I_N = 0
    for i in range(num_iter):
        \mbox{\tt\#} if the iteration was larger than or equal to 101 , I_N will equal to 70
            I_N = 70
        print(f"\nIter : {i + 1}")
        k_1v = (1/c)*(k*(v_old - v_r)*(v_old - v_t) - w_old + I_N)
        k_1_w = a^*(b^*(v_old - v_r) - w_old)
        v_mid = v_old + (h_value / 2) * k_1_v
        w_mid = w_old + (h_value / 2) * k_1_w
```

```
# calculating the K2v and K2w using mid values from Step 2 (Step 3)
       k_2v = (1 / c) * (k * (v_mid - v_r) * (v_mid - v_t) - w_mid + I_N)

- > Why would we use this method?
- 1. Easy to implement using python
- 2. It uses intermediate step (calculating the midpoint) which will reduce truncation error
- 3. It has more accurate than Euler method at same step size (h)
- 4. It is computationally cheaper than RK4 method
- ➤ Why wouldn't we use this method?
- 1. Not accurate as RK4
- 2. Twice as expensive as Euler method computationally
- 3. Not easy to be implemented manually (using paper and pen)
